Different Scopes

Global scope

The global scope is the main block of code (not the functions). The variables that are defined here are visible and accessible anywhere in the code file. Global variables can be defined/modified inside a local scope if the keyword 'global' is prior to the variable name.

Local scope

The local scope is the code for any function or lambda expression. It contains variables that are defined inside the function and these variables are only accessible inside the function/lambda expression. Any function created within the original function will also have access to the variables that are defined within the original function.
